#### Abstract

The polynomial regression (PR) technique is used to estimate the parameters of the dependent variable having a polynomial relationship with the independent variable. Normality and nonlinearity exhibit polynomial characterization of power terms greater than 2. Polynomial Regression models (PRM) with the auxiliary variables are considered up to their third order interactions. Preliminary, multicollinearity between the independent variables is minimized and statistical tests involving the Global, Correlation Coefficient, Wald, and Goodness-of-Fit tests, are carried out to select significant variables with their possible interactions. Comparisons between the polynomial regression models (PRM) are made using the eight selection criteria (8SC). The best regression model is identified based on the minimum value of the eight selection criteria (8SC). The use of an appropriate transformation will increase in the degree of a statistically valid polynomial, hence, providing a better estimation for the model.

Keywords: stem volume, polynomial regression models (PRM), normality, multicollinearity, eight selection criteria (8SC).

## 1. INTRODUCTION

According to Bechtold (2004), the stem (or bole) diameter was statistically significant and the strongest predictor in all models of tree estimations, and for some species a quadratic term was needed for model enhancement. While Hasenaeur (2006) had used modelling to predict future forest stand development, Noraini et al.(2008) had presented for tree stem biomass prediction and estimation using multiple regression models.

## Stem Biomass Volumetric Equation

The variables considered during field data collection of 130 trees are diameter at the base $\left(D_{b}\right)$, diameter at the middle $\left(\mathrm{D}_{\mathrm{m}}\right)$, diameter at the top $\left(\mathrm{D}_{\mathrm{t}}\right)$, and the stem height $(\mathrm{T})$. The cylindrical area of $\log (\mathrm{A})$ is given by formula $\pi R^{2}$, where R is the radius of the tree stem or bole. Hence, at each respective sections of the log, the area will then be known as $\mathrm{A}_{\mathrm{b}}$ (at the base), $\mathrm{A}_{\mathrm{m}}$ (at the middle) and $A_{t}$ (at the top). Since diameter is twice the radius, the corresponding cross-sectional area will then be calculated as: $A_{b}=\pi D_{b}^{2} / 4, A_{m}=\pi D_{m}^{2} / 4$ and $A_{t}=\pi D_{t}^{2} / 4$ respectively.

Area $=л R^{2} /$ bole where $R$ is radius of stem
$=\pi D^{2} / 4$ where D is the diameter $\mathrm{R}=\mathrm{D} / 2$

Figure 1. Merchantable Tree Log

The volume of the merchantable log will be the stem height multiplied by the area as shown in Figure 1 above. In this paper, based on these mensuration variables, the volume of the stem biomass is then calculated using the Newton's formula as in (1).

Newton's Formula (Fuwape et al., 2001):

$$
\begin{equation*}
V_{N w}=\frac{T}{6}\left(A_{b}+4 A_{m}+A_{t}\right) \tag{1}
\end{equation*}
$$

The objective of this study is to compare models based on the Newton's Formula using the polynomial regressions (PR) technique with significant attribution to the power terms.

## 2. METHODOLOGY

### 2.1 Data Preparation and P-value Method for Normality

In regression analysis, normality and linear relationship of data is of prime importance. Hence, normality test is initially carried out numerically (Coakes \& Steed, 2007), with the graphical method as supporting evidence (Ashish \& Muni, 1990). Normality tests are carried out in SPSS and the test statistic of the variable is given by the statistic value of Kolmogorov-Smirnov (for $\mathrm{n}>50$ ) and Shapiro Wilk (for $\mathrm{n}<50$ ). The confidence level is set at $95 \%$ with significance of $\alpha$ at $5 \%$ which is the standard percentage of the normality test.

The type of transformation will be done on any data sets by first plotting a scatter plot of the dependent variable over the independent variable. For normality and linearity, appropriate transformation values are taken to form the characterization of the polynomial terms. Driving up or driving down the ladder will depend on the concavity or convexity of the scatter plot. This paper will focus on the searching efforts for the best transformations applicable to the data sets, and optimizes the range of transformation needed. These have also become a part of models' simulations and optimization.

Transformation will involve: i) identifying the types of curvilinear data, ii) determining the types of transformation needed, and iii) exercise the procedures for Ladder-Power or Box-Cox
transformations. The ladder transformation procedure uses the data sets the power of the origin is employed, which is given by: (Devore \& Peck, 1993)

Transform value $=(\text { Original Value })^{\text {power }}$
Using the p-value from the F-statistics, data with p-value $>0.05$ are considered as normal. Several iterations are executed so to determine the best transformation required for normality. Figure 2 depicts the flowchart on the data transformation procedures executed on non-normal or nonlinear data before any model building can be developed.

Figure 2. Flow Chart on the Procedures of Data Transformations

### 2.2 Modelling and Model-Building Approach

Figure 3 depicts the modelling flowchart. Preliminary with the conceptual development of the importance of modelling, its estimations, and contributions to the real world problems, mathematical theories are applied for model building.

Figure 3: Modelling Flowchart

Figure 4. The Four Phases in Model-Building Development
Figure 4 shows the four phases of the Model-building development. Model-building techniques are exemplified and validated through tests and hypotheses. Model's validation is enhanced by simulation and optimization of values, expected to be characterized as optimal values. In this paper, the phases in model development will not be illustrated since the elimination procedures had been shown by Noraini et al., (2008) and the multicollinearity removal techniques (Noraini et al., 2010(a)).

### 2.3 Polynomial Regression Models (PRM)

Phase 1 of Model-building in Figure 4, consists of the all possible models which are made up of variables that have been prepared after undergoing the data preparation procedures of Figure 2. For simplicity, these variables are then known as the defined transformed variables.

The PR models are made of a dependent variable, V, the stem volume and single independent variables, taken from field data mensuration. The model-building is developed based on the method of multiple regressions, a statistical method of more than two independent variables as in (3),

$$
\begin{equation*}
Y_{i}=\beta_{0}+\beta_{1} \mathrm{X}_{1 \mathrm{i}}+\beta_{2} \mathrm{X}_{2 \mathrm{i}}+\ldots+\beta_{k} \mathrm{X}_{\mathrm{ki}}+\varepsilon_{\mathrm{i}} \tag{3}
\end{equation*}
$$

, where $\mathrm{i}=1,2, \ldots, \mathrm{n} ; \mathrm{Y}_{\mathrm{i}}$ is the dependent variable; $\mathrm{X}_{\mathrm{i}}, \mathrm{X}_{2 \mathrm{i}}, \ldots, \mathrm{X}_{\mathrm{ki}}$ are the independent variables; $\beta_{\mathrm{i}}$ 's are the regression coefficients with k parameters and $\varepsilon_{\mathrm{i}}$ are the residuals. As with polynomials of the order 2 (parabolic curve with quadratic terms), the model equation can be written as:

$$
\begin{equation*}
Y_{i}=\beta_{0}+\beta_{1} \mathrm{X}_{\mathrm{li}}+\beta_{11} \mathrm{X}_{\mathrm{li}}{ }^{2}+\ldots+\beta_{k} \mathrm{X}_{\mathrm{ki}}+\beta_{k k} \mathrm{X}_{\mathrm{ki}}{ }^{2}+\varepsilon_{\mathrm{i}} \tag{4}
\end{equation*}
$$

Based on say four single independent variables, the number of models then is 32 models (as shown in Table 1).

Table 1: Total Number of Possible Models

|  |  | Order of Interactions |  |  | Total number <br> of models |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Number of Variables |  | 1st | 2nd | 3rd |  |
| 1 |  | - | - | - | 4 |
| 2 | 6 | 6 | - | - | 12 |
| 3 | 4 | 4 | 4 | - | 12 |
| 4 | 1 | 1 | 1 | 1 | 4 |
| Total | 15 | 11 | 5 | 1 | 32 |

Examples of possible PRM's are shown in Table 2 whereby models from P1-P15 are without interactions, P16-P26 ( $1^{\text {st }}$ order interactions), P27-P31 ( $2^{\text {nd }}$ order interactions) and P32 ( $3^{\text {rd }}$ order interactions). The all possible PR models are listed as in the Appendix.

Table 2: All Possible Models of Four single independent Variables.

| P1 | $\mathrm{V}_{1}=\beta_{0}+\beta_{1} \mathrm{X}_{1}+\beta_{11} \mathrm{X}_{1}{ }^{2}+\varepsilon_{1}$ |
| :--- | :--- |
| P2 | $\mathrm{V}_{2}=\beta_{0}+\beta_{2} \mathrm{X}_{2}+\beta_{22} \mathrm{X}_{2}{ }^{2}+\varepsilon_{2}$ |
| P3 | $\mathrm{V}_{3}=\beta_{0}+\beta_{3} \mathrm{X}_{3}+\beta_{33} \mathrm{X}_{3}{ }^{2}+\varepsilon_{3}$ |
| P4 | $\mathrm{V}_{4}=\beta_{0}+\beta_{4} \mathrm{X}_{4}+\beta_{44} \mathrm{X}_{4}{ }^{2}+\varepsilon_{4}$ |
| $:$ | $: \quad: \quad:$ |
| P15 | $\mathrm{V}_{15}=\beta_{0}+\beta_{1} \mathrm{X}_{1}+\beta_{2} \mathrm{X}_{2}+\beta_{3} \mathrm{X}_{3}+\beta_{4} \mathrm{X}_{4}+$ <br>  <br> $\beta_{11} \mathrm{X}_{1}{ }^{2}+\beta_{22} \mathrm{X}_{2}{ }^{2}+\beta_{33} \mathrm{X}_{3}{ }^{2}+\beta_{44} \mathrm{X}_{4}{ }^{2}+\varepsilon_{15}$ |
| P16 | $\mathrm{V}_{16}=\beta_{0}+\beta_{1} \mathrm{X}_{1}+\beta_{2} \mathrm{X}_{2}+\beta_{11} \mathrm{X}_{1}{ }^{2}+\beta_{22} \mathrm{X}_{2}{ }^{2}$ <br> $+\beta_{12} \mathrm{X}_{12}+\varepsilon_{16} \quad:$ <br> $:$$\quad: \quad: \quad: \quad:$ |

| P27 | $\begin{aligned} & V_{27}=\beta_{0}+\beta_{1} X_{1}+\beta_{2} X_{2}+\beta_{3} X_{3}+\beta_{11} X_{1}^{2} \\ & +\beta_{22} X_{2}^{2}+\beta_{33} X_{3}^{2}+\beta_{12} X_{12}+\beta_{13} X_{13}+ \\ & \beta_{23} X_{23}+\beta_{123} X_{123}+\varepsilon_{27} \end{aligned}$ |
| :---: | :---: |
| : |  |
| P32 | $\begin{aligned} & \mathrm{V}_{37}=\beta_{0}+\beta_{1} \mathrm{X}_{1}+\ldots+\beta_{11} \mathrm{X}_{1}^{2}+\ldots+\beta_{12} \mathrm{X}_{12}+\ldots \\ & +\beta_{34} \mathrm{X}_{34}+\beta_{123} \mathrm{X}_{123}+\ldots+\beta_{1234} \mathrm{X}_{1234}+\varepsilon_{32} \end{aligned}$ |

One of the possible models with different variables' attributes is given by model P27:

$$
\begin{align*}
V_{27} & =\beta_{0}+\beta_{1} X_{1}+\beta_{2} X_{2}+\beta_{3} X_{3}+\beta_{11} X_{1}^{2}+\beta_{22} X_{2}^{2}+\beta_{33} X_{3}^{2}  \tag{5}\\
& +\beta_{12} X_{12}+\beta_{13} X_{13}+\beta_{23} X_{23}+\beta_{123} X_{123}+\varepsilon_{27}
\end{align*}
$$

, with $X_{1}, X_{2}$, and $X_{3}$ as the single independent variables, $X_{12}, X_{13}$ and $X_{23}$ as the 1 st order interactions, $\mathrm{X}_{123}$ is the 2 nd order interaction, and $\mathrm{X}_{1}{ }^{2}, \mathrm{X}_{2}{ }^{2}$ and $\mathrm{X}_{3}{ }^{2}$ as the polynomial term of power 2 ( or also known as the quadratic terms).
The models can then be written in a general form as:

$$
\begin{equation*}
\mathrm{V}_{\mathrm{PR}}=\Omega_{0}+\Omega_{1} \mathrm{~W}_{1}+\Omega_{2} \mathrm{~W}_{2}+\ldots+\Omega_{\mathrm{k}} \mathrm{~W}_{\mathrm{k}}+\mathrm{u} \tag{6}
\end{equation*}
$$

, where $\mathrm{V}_{\mathrm{PR}}$ is the volume, ' $W$ ' is an independent variable which represents one of these types of variables, namely, single independent, interactive, generated, transformed, quadratic terms or even dummy variables, $\Omega$ 's are the newly defined regression coefficients, and ' $u$ ' as the error terms for each respective transformed model. The number of models will depend on the number of single independent variables, given by the formula $\sum_{j=1}^{q} j\left({ }^{q} C_{j}\right)$ where ' $q$ ' is the number of single independent variables.

### 2.4 Multicollinearity Removal and Insignificant Variable Elimination

Multicollinearity is a phenomenon where there exists very strong linear or perfect relationships between the independent variables (Gujarati, 2006), and collinearity between the variables can be identified by examining the values of the correlation matrix of the independent variables. High correlation coefficients of absolute values in the range of $0.75 \geq|r| \geq 0.95$ are considered to exhibit multicollinearity effects. These multicollinearity source variables have to be dealt with first before modelling can be done, as indicated in Phase 2 of model development in Figure 3. The elimination of insignificant variables from the models is carried out using the backward elimination method. Illustrations of the backward elimination method had also been shown by Noraini et al. (2008). In this paper, multicollinearity source variables with high correlation coefficient of absolute values greater than $0.95(|r| \geq 0.95)$ are removed. The Case Types for multicollinearity removal procedures had also been illustrated by Noraini et al. (2010)(b).

### 2.5 Best Model Selection and Goodness-of-Fit Tests

Many criteria have been presented in order to select the best regression model, but none can be considered as the best one. Table 3 depicts the selection of the eight criteria ( 8 SC ) of Phase 3, used in identifying the best regression model (Ramanathan, 2002). The criteria are based on the value of sum of square error (SSE) where $n$ is the number of samples or observations, and $k+1$ ) is the number of parameters in each respective model. The model having the least value in majority of the criteria will be chosen as the best model.

Table 3. Eight Selection Criteria (8SC) for Best Model Identification

| AIC (Akaike, 1974) | $\left(\frac{S S E}{n}\right) e^{(2(k+1) / n)}$ | RICE (Rice, 1984) | $\left(\frac{S S E}{n}\right)\left[1-\left(\frac{2(k+1)}{n}\right)\right]^{-1}$ |
| :--- | :--- | :--- | :--- |
| FPE (Akaike, 1970) | $\left(\frac{S S E}{n}\right) \frac{n+(k+1)}{n-(k+1)}$ | SCHWARZ (Schwarz, <br> $1978)$ | $\left(\frac{S S E}{n}\right) n^{(k+1) / n}$ |
| GCV (Golub et al., <br> 1979) | $\left(\frac{S S E}{n}\right)\left[1-\left(\frac{k+1}{n}\right)\right]^{-2}$ | SGMASQ <br> (Ramanathan, 2002) | $\left(\frac{S S E}{n}\right)\left[1-\frac{(k+1)}{n}\right]^{-1}$ |
|  <br> Quinn, 1979) | $\left(\frac{S S E}{n}\right) \ln n^{2(k+1) / n}$ | SHIBATA (Shibata, <br> 1981) | $\left(\frac{S S E}{n}\right) \frac{n+2(k+1)}{n}$ |

The best model will undergo the goodness-of-fit tests of Phase 4 in Figure 4, which comprises of the normality and randomness tests on the models' residuals. Without violating the assumptions in regression analysis, further simulations of the best model will provide a better prediction for future forest planning strategy and management.

## 3. MODELING RESULTS AND ANALYSES

### 3.1 Normality and Descriptive Statistics

The data variables are measured from 130 trees non-destructively, as defined in Table 3. Normality tests are done and transformations are carried out using Ladder-Power on the nonnormal data. Table 4 depicted the defined variables, before and after transformations.

| Table 4. Definition of Variables Before and After Transformation |  |  |  |
| :---: | :---: | :---: | :---: |
| Variable | Definition | Transformation | Transformed Variables |
| $\mathrm{V}_{\mathrm{Nw}}$ | Stem Volume. $\left(\mathrm{m}^{3}\right): \quad \mathrm{Nw}-$ Newton | $\mathrm{V}_{\mathrm{Nw}}$ | V |
| $\mathrm{D}_{\mathrm{t}}$ | Diameter at top of trunk | $\mathrm{D}_{\mathrm{t}}{ }^{3.7}$ | X1 |
| $\mathrm{D}_{\mathrm{m}}$ | Diameter at middle of trunk | $\mathrm{D}_{\mathrm{m}}{ }^{4.5}$ | X2 |
| $\mathrm{D}_{\mathrm{b}}$ | Diameter at the base of trunk | $\mathrm{D}_{\mathrm{b}} / \mathrm{T}$ | X3 |
| T | Tree height (m) | T | $\mathrm{X}_{4}$ |

From Table 5, the p-values of variable $D_{t}$ increase in the variable power range of 1.5-3.5, before decreases to the value of 4.5 . The optimal (highest) p -value is 0.034 , and the variable power is thus focused at 3.5.

| Table 5. Normality Test Using Kolmogorov Smirnov on Variable $D_{t}$ |  |  |  | Table 6. Normality Test on Focus Optimal value of Variable $D_{t}$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Transformed Variable | Kolmogorov-Smirnov |  |  | Transformed <br> Variable | Kolmogorov-Smirnov |  |  |
|  | Statistics | df | $\mathrm{p}-$ |  | Statistics | df | p-value |
|  |  |  | value |  | 0.078 | 130 | 0.049 |
| $\mathrm{D}_{\mathrm{t}}{ }^{1.5}$ | 0.148 | 130 | 0.000 | $\mathrm{D}_{\mathrm{t}}{ }^{3.7}$ | 0.076 | 130 | 0.061 |
| $\mathrm{D}_{\mathrm{t}} \mathrm{D}^{2.5}$ | 0.115 | 130 | 0.000 | $\mathrm{D}_{\mathrm{t}} \mathrm{D}^{3.8}$ | 0.078 | 130 | 0.051 |
| $\mathrm{D}_{\mathrm{t}} \mathrm{D}_{\mathrm{t}}{ }^{\text {3.5 }}$ | 0.082 | 130 | 0.034 | $\mathrm{D}_{\mathrm{t}}{ }^{3.9}$ | 0.080 | 130 | 0.043 |

Transformation power range is then chosen between 3.5-4.5. Referring to Table 6, variable $D_{t}$ has reached the optimal normality value of 0.061 (highest) at the transformation value of 3.7. The second decimal digit will lie between 3.7-3.8. Similar procedures are executed on the other variable, $D_{m}$, and a generated variable, $D_{b} / T_{h}$, has been created for normality. Table 7 below depicts the descriptive statistics of the models' transformed variables. All the transformed
variables have turned to normal since the significant p -value are more than 0.05 . The data sets can then be used for further regression analysis.

Table 7. Descriptive Statistics of Transformed Variables

| Defined Variables | Transformed Variables |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  | V | X 1 | X 2 | X 3 | X 4 |
| Mean | 0.9215 | 0.1360 | 0.1081 | 0.1070 | 6.1303 |
| Variance | 0.133 | 0.005 | 0.004 | 0.000 | 0.896 |
| Std. Deviation | 0.3643 | 0.0713 | 0.0628 | 0.0144 | 0.9466 |
| Minimum | 0.18 | 0.01 | 0.00 | 0.07 | 3.78 |
| Maximum | 1.96 | 0.40 | 0.33 | 0.15 | 8.23 |
| Skewness | -0.020 | 0.331 | 0.332 | 0.624 | -0.257 |
| Kurtosis | -0.147 | 0.602 | 0.158 | 0.905 | -0.378 |
| Kolmogorov-Smirnov | 0.068 | 0.076 | 0.060 | 0.065 | 0.043 |
| Kolmogorov-Smirnov (sig. p-value) | 0.200 | 0.061 | 0.200 | 0.200 | 0.200 |
| Standard error (s.e.) of Skewness is 0.212. <br> 0.422. |  |  |  |  |  |

### 3.2 Multicollinearity Removal and Backward Elimination Method

In Phase 2 of model-building, multicollinearity source variables with high correlation coefficient of absolute values greater than $0.95(|\mathrm{r}| \geq 0.95)$ are thus removed. The Case Types for multicollinearity removal procedures had been illustrated by Noraini et al. (2010)(b).The elimination of insignificant variables from the models is carried out using the backward elimination method.

These procedures employed in Phase 2 will not be dealt with in detail, but then suffices to include the coefficient correlation matrix of the best model before and after multicollinearity removal and elimination of insignificant variables being carried out (Table 8, Table 9 and Table 10) respectively. The highlighted values in Table 8 indicate examples of high correlation values exhibiting multicollinearity effects of the independent variables (X1, X2, X12) which then result in the first multicollinearity removal of variable X12.

Table 8: Correlation Coefficient Matrix of Model P26.0

|  | $Y$ | X1 | X2 | X3 | X4 | X12 | X13 | X14 | X23 | X24 | X34 | X11 | X22 | X33 | X44 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Y | 1 |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| X1 | 0.897 | 1 |  |  |  |  |  |  |  |  |  |  |  |  |  |
| X2 | 0.884 | 0.917 | 1 |  |  |  |  |  |  |  |  |  |  |  |  |
| X3 | 0.116 | 0.219 | 0.225 | 1 |  |  |  |  |  |  |  |  |  |  |  |
| X4 | 0.859 | 0.641 | 0.619 | -0.332 | 1 |  |  |  |  |  |  |  |  |  |  |
| X12 | 0.807 | 0.904 | 0.922 | 0.224 | 0.522 | 1 |  |  |  |  |  |  |  |  |  |
| X13 | 0.841 | 0.969 | 0.896 | 0.413 | 0.503 | 0.908 | 1 |  |  |  |  |  |  |  |  |
| X14 | 0.940 | 0.979 | 0.904 | 0.101 | 0.747 | 0.904 | 0.919 | 1 |  |  |  |  |  |  |  |
| X23 | 0.834 | 0.901 | 0.975 | 0.393 | 0.497 | 0.927 | 0.934 | 0.861 | 1 |  |  |  |  |  |  |
| X24 | 0.924 | 0.908 | 0.982 | 0.117 | 0.714 | 0.924 | 0.859 | 0.931 | 0.932 | 1 |  |  |  |  |  |
| X34 | 0.905 | 0.786 | 0.770 | 0.459 | 0.677 | 0.689 | 0.814 | 0.791 | 0.794 | 0.773 | 1 |  |  |  |  |
| X11 | 0.789 | 0.936 | 0.838 | 0.211 | 0.516 | 0.954 | 0.931 | 0.929 | 0.848 | 0.844 | 0.673 | 1 |  |  |  |
| X22 | 0.783 | 0.849 | 0.937 | 0.210 | 0.505 | 0.981 | 0.853 | 0.853 | 0.934 | 0.937 | 0.662 | 0.888 | 1 |  |  |
| X33 | 0.095 | 0.200 | 0.202 | 0.995 | -0.342 | 0.209 | 0.399 | 0.082 | 0.374 | 0.094 | 0.441 | 0.199 | 0.194 | 1 |  |
| X44 | 0.855 | 0.626 | 0.604 | -0.334 | 0.995 | 0.518 | 0.485 | 0.742 | 0.479 | 0.709 | 0.666 | 0.512 | 0.501 | -0.341 | 1 |

Subsequent five multicollinearity source variables (X1, X2, X12, X11, X44) are being removed have resulted in the correlation coefficient matrix of model P26.5.0 as shown in Table 9. Table 9 also shows the absence of high multicollinearity variables in the model where there are no more correlation coefficients of more than 0.95 exist in the model. The next step will be the process of eliminating insignificant variables from the model using the backward elimination method.

Table 9: Correlation Coefficient Matrix of Model P26.5.0

|  | $Y$ | $X 3$ | $X 4$ | $X 13$ | $X 14$ | $X 23$ | $X 24$ | $X 34$ | $X 11$ | $X 22$ |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Y | 1 |  |  |  |  |  |  |  |  |  |
| X3 | 0.115 | 1 |  |  |  |  |  |  |  |  |
| X4 | 0.858 | -0.331 | 1 |  |  |  |  |  |  |  |
| X13 | 0.840 | 0.412 | 0.502 | 1 |  |  |  |  |  |  |
| X14 | 0.940 | 0.101 | 0.746 | 0.919 | 1 |  |  |  |  |  |
| X23 | 0.834 | 0.393 | 0.497 | 0.934 | 0.861 | 1 |  |  |  |  |
| X24 | 0.923 | 0.116 | 0.714 | 0.859 | 0.931 | 0.932 | 1 |  |  |  |
| X34 | 0.905 | 0.459 | 0.677 | 0.814 | 0.791 | 0.794 | 0.773 | 1 |  |  |
| X11 | 0.788 | 0.210 | 0.516 | 0.931 | 0.929 | 0.848 | 0.844 | 0.673 | 1 |  |
| X22 | 0.782 | 0.210 | 0.505 | 0.853 | 0.853 | 0.934 | 0.937 | 0.662 | 0.888 | 1 |

The procedures of eliminating insignificant variables are then carried out as indicated in Table 10 below. Insignificant variables having the highest p -value or the least absolute value of the t statistics will be eliminated. It can be seen that variables ( $\mathrm{X}_{13}, \mathrm{X}_{4}$, and $\mathrm{X}_{11}$ ) are subsequently to be removed since having p -values of more than 0.05 , and hence they are not significant. Table 11 depicts the final matrix for the best model whereby all the remaining variables in the model are significant with their $p$-values less than 0.05 ( $\alpha \leq 5 \%$ ).

Table 10: Insignificant Variables Eliminated From Model P26.5.0

### 3.3 Best Model Regression Equation

The best model from the 8 SC is based on the ( $k+1$ ) parameters, and fulfills the least value of most of the criteria (Ramanathan, 2002). Table 12 signifies the comparisons of the PR models based on the eight selection criteria. It can be seen the best PR model is represented by the model P26.5.3 with five multicollinearity removals and three insignificant variables eliminated.

Table12. Comparisons of the Best PR Models Using Newton's Equation

| Model | $\mathrm{k}+1$ | SSE | AIC | FPE | GCV | HQ | RICE | SCHWARZ | SGMASQ | SHIBATA |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| P26.5.3 | 7 | 0.059 | 5.058 | 5.059 | 5.073 | 5.386 | 5.090 | 5.903 | 4.800 | 5.031 |
|  |  |  | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ |
| P31.9.4 | 6 | 0.078 | 6.582 | 6.583 | 6.597 | 6.946 | 6.612 | 7.514 | 6.292 | 6.556 |
|  |  |  | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ |
| P32.10. | 7 | 0.063 | 5.375 | 5.376 | 5.391 | 5.723 | 5.409 | 6.273 | 5.101 | 5.346 |
| 3 |  |  | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ | $\mathrm{E}^{-04}$ |

The goodness-of-fit tests comprises of the randomness test and normality test. Randomness test is to determine that the residuals are normally distributed and normality test on the Kolmogorov-Smirnov statistics is to ensure that the normality assumptions are not violated. Since the sample size is 130 , the random statistic, $R$ is based on the normal ( z ) distribution. The null hypothesis is accepted since model P26.5.3 has zero mean of the residuals as shown by the scatterplot of the standardized residuals in Table 13. This implies that the residuals are independent and randomly distributed.

Table 13: Scatterplot and Histogram of the Regression Standardized Residuals.

With a significance level of more than $0.05(\alpha>0.05)$, the normality test on the residuals gave the Kolmogorov-Smirnov statistics ( 0.192 ) of $p$-value $(0.052)>0.05$. From the good-of-fit tests and the plots, the assumptions of randomness and normality of the residuals have therefore been satisfied.

The best polynomial regression model is thus given by Table 11 as:-
$P_{26.5 .3}=-0.22-4.09 X_{3}-4.136 X_{2}{ }^{2}+0.186 X_{14}-3.452 X_{23}+0.400 X_{24}-1.909 X_{34}$

Substituting the defined variables back into equation (7), the best model equation is thus:
$\mathrm{P}_{26.5 .3}=-0.22-4.09 \mathrm{D}_{\mathrm{b}} / \mathrm{T}-4.136\left(\mathrm{P}^{4.5}\right)^{2}+0.186 \mathrm{Q}^{3.7} \mathrm{~T}-3.452 \mathrm{R}_{\mathrm{m}}^{4.5} \mathrm{D}_{\mathrm{b}} / \mathrm{T}+0.400 \mathrm{R}_{\mathrm{m}}^{4.5} \mathrm{~T}-1.909 \mathrm{Q}$

Equation (8) signifies the appropriateness of the power transformation used in normalizing the variables before regression analysis. The range of integers in the model equation is mathematically from 3.7-9.0.

## 4. DISCUSSIONS AND CONCLUSIONS

Power Transformation in the form of integers is executed to normalize and linearize the data sets. The resultant model equation has polynomial characterization greater than 2. Previous studies had indicated that complexities of using polynomial regression in regression algorithm where higher orders of the polynomials are concerned (Dam et al., 2000; Ekpenyong et al., 2008). The polynomial relationships of the independent variables with the dependent can be transformed using the p-value method of the normality tests on the variables. Remedial techniques in minimizing multicollinearity effects are applied to obtain a robust model, further followed by the elimination of insignificant variables in the model. The eight selection criteria is effective in identifying the best model, where formally the criteria used is based on the $\mathrm{R}^{2}$ or the adjusted- $\mathrm{R}^{2}$ for model selection. Comparisons between the Newton's multiple regression models by Noraini et al.(2008) and Noraini et al.(2010(b)), based on the least 8SC, have appeared to represent an improved estimation using polynomial regression models (PRM) for volumetric stem biomass. Diameters at the base, middle, top and tree height have again signified as the main contributors towards the stem volume estimation.
