# Optimization of Submerged Arc Welding process Parameters Using PCA-Based Taguchi Approach. 

P.Sreeraj*<br>* Department of Mechanical Engineering, Younus College of Engineering and Technology, Kollam, 691010, INDIA.

Received 28 October 2016; accepted 8 December 2016, available online 8 December 2016

#### Abstract

The present study highlights optimization of submerged arc welding (SAW) process parameters in order to obtain optimal parametric combination to yield favorable weld bead geometry in mild steel plates IS 2062. Taguchi's $\mathrm{L}_{25}$ orthogonal array ( OA ) design and signal- to- noise ratio ( $\mathrm{S} / \mathrm{N}$ ratio) have been used in this study. Penetration (P), bead width (W), reinforcement (R) and Percentage dilution (D) are selected as objective functions. The principal component analysis coupled with Taguchi method has been applied to solve this multi response optimization problem. Carried out to meet basic assumption of Taguchi method, individual response correlations have been eliminated first by means of principal component analysis (PCA).The correlated responses then transformed into uncorrelated or independent quality indices called principal components. Based on individual principal components a Multi-response Performance Index (MPI) has been introduced to derive an equivalent single objective function which has been optimized using Taguchi method. Developed model has been checked for adequacy and significance based on ANOVA test. Accuracy of optimization was confirmed by conducting confirmation tests. The study highlights effectiveness of the proposed method for solving multi-objective optimization of submerged arc weld.

Keywords: SAW, Taguchi's concept, orthogonal array, bead geometry, PCA

## 1. Introduction

Submerged arc welding is a multi-factor, multiobjective manufacturing process. Because of easy control of process variables, high quality, deep penetration and smooth finish, it is widely preferred in ship building industry. In the present work, the effect of voltage, current, nozzle to plate distance and welding speed on bead geometry have been studied. Mechanical and chemical properties of good weld depend on bead geometry. Bead geometry has a direct effect on process parameters. Because of this, it is necessary to study the relationship between process parameters and weld bead geometry.

Fig 1 shows weld bead geometry. Mechanical strength of weld metal is highly influenced by the composition of metal but also by weld bead shape. This is an indication of bead geometry. It mainly depends on welding current; welding speed, arc voltage etc [1]. This paper highlights the study carried out to develop mathematical models to optimize weld bead geometry, on bead on plate welding by submerged arc welding SAW.

In this study Taguchi method coupled principal component analysis (PCA) is used for solving the multi optimization problem. This method utilizes a well balanced experimental design with limited number of experimental runs called orthogonal array (OA) and signal to noise ratio ( $\mathrm{S} / \mathrm{N}$ ratio) which serve the objective function to be optimized, within experimental domain. The traditional Taguchi method cannot solve multiobjective optimization problems.

The original Taguchi method is designed and utilized to optimize a single quality characteristic or response. Furthermore, optimization of multiple objectives or responses is much more difficult than optimization of a single objective. Improving one particular quality characteristic would likely cause deliberate degradation of the other critical quality characteristics. It leads to increment of uncertainty at the time of decision-making process. In order to overcome this difficulty, the Taguchi method coupled with principal component analysis used to solve the optimization problem in this study.

Fig 1 weld bead geometry

## 2. Taguchi Method

Taguchi method uses a special type of design of orthogonal arrays (OA) to study the entire parameter space with smaller number of experiments. The
experimental results are then transferred to signal- tonoise ( $\mathrm{S} / \mathrm{N}$ ) ratio. This ratio can be used to measure the quality characteristics deviating from desired values. Usually there are three categories of in the analysis of the signal-to-noise ratio that is the lower- the- better (LB), higher- the- better (HB) and nominal- the- best (NB) [2]. Regardless of category of quality characteristics larger signal -to-noise ratio corresponds to the better quality characteristics. The optimal process parameters are the levels with highest signal-to-noise ratio. Once the experimental data is normalized using $\mathrm{NB} / \mathrm{LB} / \mathrm{HB}$ criteria; normalized value lies between zero and one. Zero represented worst quality and one represented most satisfactory quality. Since $\mathrm{S} / \mathrm{N}$ ratio is expressed as mean (signal) to the noise (deviation from the target); maximizing $\mathrm{S} / \mathrm{N}$ ratio ensures minimum deviation and hence it is ( $\mathrm{S} / \mathrm{N}$ ratio) to be maximized.

S/N ratio for Nominal- the- best (NB)
$\eta=10 \ln _{10} \frac{1}{n} \sum_{i=1}^{n} \frac{\mu^{2}}{\sigma^{2}}$
S/N ratio for Lower- the- better (LB)
$\eta=-10 \ln _{10} \frac{1}{n} \sum_{i=1}^{n} Y_{i}^{2}$
S/N ratio for Higher- the- better (HB)
$\eta=-10 \ln _{10} \frac{1}{n} \sum_{i=1}^{n} \frac{1}{Y_{i}^{2}}$
$Y_{i}=$ value of the quality characteristic at $\boldsymbol{i}^{\text {th }}$ setting.
$N=$ Total number of trial runs at $\boldsymbol{i}^{\text {th }}$ setting.
$\sigma=$ standard deviation.
$\mu=$ Mean.

## 3. Principal Component Analysis (PCA)

PCA is a way of identifying patterns in the correlated data, and expressing the data in such a way so as to highlight the similarities and differences. The main advantage of PCA is that once the patterns in data have been identified, the data can be compressed, i.e., by reducing the number of dimensions, without much loss of information. The entire work is based on the assumption that there is no interaction effect of the process parameters involved. The methods involved in PCA are given below [3]:

1. Getting the data
2. Normalization of data.
3. Calculation of covariance matrix.
4. Interpretation of covariance matrix.

The normalized data have been utilized to construct a variance -covariance matrix M., which is illustrated as below:

$$
M=\left[\begin{array}{cccc}
N_{1,1} & N_{1,2} & \cdots & N_{1, \mu}  \tag{4}\\
N_{2,1} & N_{2,2} & \cdots & N_{2, p} \\
\cdot & \cdot & \cdots & \cdot \\
\cdot & \cdot & \cdots & \cdot \\
N_{q, 1} & N_{q, 2} & \cdots & N_{q, p}
\end{array}\right]
$$

Where

$$
\begin{equation*}
N_{k, l}=\frac{\operatorname{Cov}\left(Y_{i, k}^{*}, Y_{i, l}^{*}\right)}{\sqrt{\operatorname{Var}\left(Y_{i, k}^{*}\right), \operatorname{Var}\left(Y_{i, l}^{*}\right)}} \tag{5}
\end{equation*}
$$

In which $u$ stands for the number of quality characteristics and $P$ stands for the number of experimental runs. Then eigenvectors and Eigen values of matrix $M$ can be computed which can be denoted by $\bar{V}_{j}$ and $\lambda_{j}$ respectively.
In PCA the eigenvector $\bar{V}_{j}$ represents the weighing factor of $j$ number of quality characteristic of the $j^{t h}$ principal component. For example $Q_{j}$ represents $j^{\text {th }}$ quality characteristic, the $j^{\text {th }}$ principal component $\psi_{j}$ can be computed as quality vector with required quality characteristics.

$$
\begin{equation*}
\psi_{j}=V_{1,} Q_{1}+V_{2 j} Q_{2}+\cdots \cdots \cdots+V_{i j} Q_{j}=\overline{V_{j}} \bar{Q} \tag{6}
\end{equation*}
$$

It is to be noted that every principal component $j \psi$ represents a certain degree of explanation of the variation of quality characteristics, namely the accountability proportion (AP). When several principal components are accumulated, it increases the accountability proportion of quality characteristics. This is denoted as cumulative accountability proportion (CAP).

If a quality characteristic $j Q$ strongly dominates in the $j^{\text {th }}$ principal component, this principal component becomes the major indicator of such a quality characteristic. It should be noted that one quality indicator may often represent all the multi-quality characteristics. Selection of individual principal components (j $\psi$ ), those to be included in the composite
quality indicator $\psi$, depends on their individual accountability proportion. But the case where to deal with more than two principal components in which accountability proportion of all principal component bear remarkable values those cannot be neglected; the problem of computing composite principal component arises There are various formulas on aggregation of individual principal components as reported in literature to compute a (MPI) multi-response performance index(composite principal component). There is no strong mathematical background to compute this MPI. Therefore, it depends on the discretion of decision makers. In this study MPI is converted to quality loss indicator which is a comparison to ideal that is to be minimized to get optimized result.

## 4. Experimentation

The experiment was designed based on Taguchi's method. The experiment was conducted as per $\mathrm{L}_{25}$ orthogonal array using COLTON submerged arc welding equipment (SAW). Bead on plate welding was carried on IS 2062 grade carbon steel. Test plates of size $300 \times 200$ x 10 mm were cut from steel plate of and one of the surfaces are cleaned to remove oxide and dirt before welding with EH 14 wire of 4 mm diameter in the form of coil. ASK74S granular flux is baked for two hours and tip of the welding wire, arc and the welding joint in the work piece are covered by this heated flux before welding. No Inert gas is used for welding. Two transverse specimens were cut from each weldment and standard metallographic procedures were adopted. Bead profiles were drawn using a reflective type profile projector [4]. Chemical composition of base metal and filler wire is shown in Table 1.

Table 1 Chemical Composition of Base Metal and Filler Wire

|  |  | Elements, Weight \% |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Materials | C | Si | Mn | P | S | Al | Cr | Mo | Ni |
| IS 2062 | 0.150 | 0.160 | 0.870 | 0.015 | 0.016 | 0.031 | - | - | - |
| EH 14 | 0.12 | 0.1 | 0.172 | 0.03 | 0.03 | - | - | - | - |

## 5. Plan of Investigation

The research work was carried out through following steps [5]:

1. Identifying the quality characteristics and process parameters to be evaluated.
2. Determining number of levels for the process parameters and possible interactions between process parameters.
3. Select appropriate orthogonal array and assign process parameters to the orthogonal array.
4. Conduct experiment as per arrangement of orthogonal array.
5. Analyse the experiments through PCA based Taguchi approach.
6. Select the optimum level of process parameters.
7. Conducting confirmation experiment.

### 5.1 Development of orthogonal array

Welding parameters and their levels are shown in Table 2. The experimental design based on an orthogonal array (OA). It allows the effect of each welding process parameters at different levels to be separated out. The selection of appropriate orthogonal array is based on total degree of freedom (dof). The degrees of freedom are defined as the number of comparisons between process parameters that must be able to determine which level is better and specifically how much better is [6]. The degrees of freedom for the orthogonal array should be greater than or at least equal to, those for the process parameters. In this study $\mathrm{L}_{25}$ orthogonal array with 8 columns and 18 rows was used. This is shown in Table 3.

Table 2 Welding Parameters and their Levels

| Parameters | Unit | Notation | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Welding Current | A | I | 350 | 420 | 500 | 580 | 650 |
| Welding Speed | $\mathrm{mm} / \mathrm{min}$ | S | 30 | 40 | 50 | 60 | 70 |
| Voltage | v | V | 24 | 26 | 28 | 30 | 32 |
| Nozzle to plate distance | mm | T | 30 | 32.5 | 35 | 37.5 | 40 |

### 5.1 Development of orthogonal array

Welding parameters and their levels are shown in Table 2. The experimental design based on an orthogonal array (OA). It allows the effect of each welding process parameters at different levels to be separated out. The selection of appropriate orthogonal array is based on total degree of freedom (dof). The degrees of freedom are
defined as the number of comparisons between process parameters that must be able to determine which level is better and specifically how much better is [6]. The degrees of freedom for the orthogonal array should be greater than or at least equal to, those for the process parameters. In this study $\mathrm{L}_{25}$ orthogonal array with 8 columns and 18 rows was used. This is shown in Table 3.

Table 3 Orthogonal array

| Trial Number | Design Matrix |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | I | S | V | T |
| 1 | 1 | 1 | 1 | 1 |
| 2 | 1 | 2 | 2 | 2 |

| 25 | 5 | 5 | 4 | 3 |

### 5.2 Conducting experiments as per orthogonal array

In this work Twenty five experimental runs were allowed as per the orthogonal array for the estimation of parameters on bead geometry as shown Table 3 at
random. At each run settings for all parameters were disturbed and reset for next deposit [7]. This is very essential to introduce variability caused by errors in experimental set up. A large sheet of steel w is used to carry experiments. This is to achieve required parametric combination in each set up.

### 5.3 Recording of Responses

For measuring the weld bead geometry, the transverse section of each weld overlays was cut using band saw from mid length. Position of the weld and end faces were machined and grinded. The specimen and faces were polished and etched using a 5\% nital solution to display bead dimensions. The weld bead profiles were traced using a reflective type optical profile projector.

Then the bead dimension such as depth of penetration height of reinforcement and weld bead width were measured using tool maker's microscope [8]. The bead profiles traced using AUTO CAD software in order to measure percentage of dilution , which is the area of penetration (B) divided by total area of wed (A+B) as shown in Fig 1. The measured weld bead dimensions and percentage of dilution is shown in Table 4.

Table 4 Orthogonal array and Observed Values of weld Bead Geometry

| Trial No. | Design Matrix |  |  |  | Bead Parameters |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## 6. Optimization of SAW Process

Assuming, the number of experimental runs in Taguchi's OA design is $m$, and the number of quality characteristics is $n$. The experimental results can be expressed by the following series [9]:
$X_{1}, X_{2}, X_{3}, \cdots \cdots \cdots, X_{i}, \cdots \cdots \cdots \cdots, X_{m}$

Here,
$X_{1}=\left\{X_{i}(1), \quad X_{i}(2), \quad X_{i}(3), \ldots \ldots \ldots \ldots \quad X_{i}(k) \ldots \ldots \ldots \quad X_{i}(n)\right\}$
$X_{i}=\left\{X_{i}(1), \quad X_{i}(2), \quad X_{i}(3), \ldots \ldots \ldots \ldots \quad X_{i}(k) \ldots \ldots \ldots X_{i}(n)\right\}$
-
$X_{m}=\left\{X_{m}(1), \quad X_{m}(2), \quad X_{m}(3), \ldots \ldots \ldots \ldots \quad X_{m}(k) \ldots \ldots \ldots \quad X_{m}(n)\right\}$
Here $\boldsymbol{X}_{i}$ represents $\boldsymbol{i}^{\text {th }}$ experimental results and is called the comparative sequence in grey relational analysis.

Let be $X_{0}$ be the reference sequence:
.Let,
$X_{0}=\left\{X_{0}(1), \quad X_{0}(2), \quad X_{0}(3), \ldots \ldots \ldots \ldots \quad X_{0}(k) \ldots \ldots \ldots \quad X_{0}(n)\right\}$

The value of the elements in the reference sequence means the optimal value of the corresponding quality characteristics. $X_{0}$ and $X_{i}$ both includes n elements and $\quad X_{0}(k)$ and $X_{i}(k)$,represent the numeric value of $\boldsymbol{K}^{\text {th }}$ element in the reference sequence and the comparative sequence., respectively $, k=1,2,3, \ldots$ $\qquad$ ..n.

### 6.1 Normalization of responses.

When the range of the series is too large or the optimal value of quality characteristics is too enormous, it will cause influence of some factors to be ignored. The original experimental data must be normalized to eliminate such effect [10]. There are three different type of normalisation such as lower- -the- better, higher- thebetter and nominal- the -best; which is shown by equations (7), (8) and (9).

LB (lower-the-better):

$$
\begin{equation*}
X_{i}^{*}(k)=\frac{\min X_{i}(k)}{X_{i}(k)} \tag{7}
\end{equation*}
$$

HB (higher-the -better):

$$
\begin{equation*}
X_{i}^{*}(k)=\frac{X_{i}(k)}{\max X_{i}(k)} \tag{8}
\end{equation*}
$$

NB (nominal-the -best):

$$
\begin{equation*}
X_{i}^{*}(k)=\frac{\min \left\{X_{i}(k), X_{o b}(k)\right\}}{\max \left\{X_{i}(k), X_{o b}(k)\right\}} \tag{9}
\end{equation*}
$$

$$
\begin{aligned}
& \mathrm{I}=1,2,3, \ldots \ldots \ldots \ldots . . . . . . . . . . . . . . . . . ., ~ m ; \\
& \mathrm{k}=1,2,3, \ldots \ldots . . . . . . . . . . . . . . . . . . . . ., ~ n ~ \\
& \text {, n }
\end{aligned}
$$

$X_{i}^{*}(k)=$ normalized value data of the $k^{\text {th }}$ element in the $\boldsymbol{i}^{\text {th }}$ sequence.
$X_{o b}(k)=$ desired quality characteristic. After data normalization, the value of $X_{i}^{*}(k)$ will be between 0 and 1.The series $X_{i}^{*}, \mathrm{i}=1,2,3 \ldots . . . . . . . . . ., \mathrm{m}$ can be viewed as the comparative sequence used in the grey relational analysis.

### 6.2 Checking correlation between two quality characteristics.

$Q_{i}=\left\{X_{0}^{*}(i), X_{1}^{*}(i), X_{2}^{*}(i) \cdots \cdots \cdots \cdots X_{i}^{*}(i)\right\}$

Where,
$\mathrm{i}=1,2,3$. $\qquad$ .n.
It is the normalized series of the $\boldsymbol{i}^{\text {th }}$ quality characteristic .The correlation coefficient between quality characteristic is given by;
$\rho_{j k}=\frac{\operatorname{Cov}\left(Q_{j}, Q_{k}\right)}{\sigma_{q_{j},} \sigma_{q_{k}}}$
$J=1,2,3 \ldots . .$. n
$K=1,2,3 \ldots \ldots, \mathrm{n}$
$j \neq k$

Here $\boldsymbol{\rho}_{j k}$ is the correlation coefficient between quality characteristics j and quality characteristic k ; $\operatorname{Cov}\left(Q_{j}, Q_{k}\right) \quad$ is the covariance of quality characteristic $j$ and $k ; \sigma_{q_{j}}$ and $\sigma_{q_{k}}$ are the standard deviation of quality characteristic $j$ and quality characteristic $k$, respectively.
The correlation coefficient is checked by testing following Hypothesis:

$$
\left\{\begin{array}{l}
H_{0}: \rho_{j k}=0(\text { There is no correlation }) \\
H_{1}: \rho_{j k} \neq 0(\text { There is correlation })
\end{array}\right.
$$

### 6.3 Calculation of principal component score

1. Calculate the Eigen value $\lambda_{k}$ and corresponding Eigen vector $\beta_{k}(\mathrm{k}=1,2,3 \ldots$.$) from the$ correlation matrix formed by all quality characteristics.
2. Calculate principal component scores of the normalized reference sequence and comparative sequence using the following equation.
$\boldsymbol{i}^{\text {th }}, \quad \mathrm{i}=0,1,2, \ldots \ldots . \mathrm{m} ; \mathrm{k}=1,2,3 \ldots . . \mathrm{n}$.
$Y_{i}(k)$ is the principal component score of the $k^{\text {th }}$ element in $i^{\text {th }}$ series.
$X_{i}^{*}(j)$ is the normalized value of the $j^{\text {th }}$ element in the $\boldsymbol{i}^{\text {th }}$ sequence, and is $\boldsymbol{\beta}_{k j}$ the $\boldsymbol{j}^{\text {th }}$ element of eigenvector $\beta_{k}$.
3. Accountability proportion of individual principal components has been treated as individual priority weights. Finally, multi-response performance index (MPI) is calculated. The quality $\operatorname{loss} \Delta_{0, j}(\mathrm{k})$,compared to that of ideal index is calculated by following equation.

$$
\Delta_{0, i}(k)=\left\{\begin{array}{l}
\left|X_{o}^{*}(k)-X_{i}^{*}(k)\right|,\left(\begin{array}{ll}
\text { no } & \text { significant correlation }) \\
\left|Y_{0}(k)-Y_{i}(k)\right|,(\text { significant correlation })
\end{array}\right.
\end{array}\right.
$$

Optimal setting is then evaluated by minimizing this $\Delta_{0, i}(k)$ quality loss estimate) by using Taguchi method

## 7. Data Analysis and Evaluation of Optimal Setting

Experimental data in Table 4 has been normalized using equation (7), (8) and (9). For dilution and penetration higher -the -better (HB), for bead width and reinforcement lower the better (LB) criterion have been selected. The normalized value is shown in Table 5.

Table 5 Normalized data

| SL No | $\mathbf{W}$ | $\mathbf{P}$ | $\mathbf{R}$ | $\mathbf{D}$ |

Table 7 Correlation check (\# significant correlation)

| Sl No | Correlation between <br> responses | Pearson's correlation <br> coefficient | Comments | P-value |
| :---: | :---: | :---: | :--- | :---: |
| $\mathbf{1}$ | Bead width and <br> penetration | 0.3876 | Both are correlated | 0.0556 |
| $\mathbf{2}$ | Bead width and <br> reinforcement | 0.7754 | Both are correlated | $0.0000^{\#}$ |
| $\mathbf{3}$ | Bead width and dilution | -0.6649 | Both are correlated | $0.0003 \#$ |
| $\mathbf{4}$ | Penetration and <br> reinforcement | -0.6276 | Both are correlated | $0.0008 \#$ |
| $\mathbf{5}$ | Penetration and dilution <br> Reinforcement and <br> dilution | -0.7407 | Both are correlated | 0.1998 |
|  |  | Both are correlated | $0.0000 \#$ |  |

After normalization, a check has been mode to verify whether the responses i.e., quality indices are correlated or not. The correlation coefficient between penetration and dilution becomes $-0.2683(\mathrm{p}$ value $=0.1998)$, which indicates that the responses are highly correlated .The coefficient of correlation, between two responses has been calculated
using equation (10)). Table 6 represents the values of these independent principal components for 25 experimental runs. Table 7 represents Pearson's coefficient between the responses. In all cases non-zero value of correlation coefficient indicates that all response features are correlated to each other Table 8 shows correlation matrix and Eigen values.

Table 8 Analysis of correlation matrix, Eigen vectors, Eigen values, accountability proportion (AP), cumulative accountability portion (CAP) computed under four major quality indicators.

|  | $\Psi_{1}$ | $\Psi_{2}$ | $\Psi_{3}$ | $\Psi_{4}$ |
| :---: | :---: | :---: | :---: | :---: |
| Eigen value | 2.7782 | 1.0052 | 0.2166 | 0.0000 |
|  | $[-0.547]$ | [0.398 | $[0.205]$ | $[-0.707]$ |
|  | -0.547 | 0.398 | 0.205 | -0.707 |
| Eigen vector | -0.525 | 0.313 | 0.791 | 0.000 |
|  | -0.355 | 0.756 | -0.538 | 0.000 |
|  |  |  |  |  |
| Proportion (AP) | 0.695 | 0.251 | 0.054 | 0.000 |
| Cumulative (CAP) | 0.695 | 0.946 | 1.000 | 1.000 |

In order to eliminate response correlations, PCA analysis has been applied to derive multi response index (MPI) using the following equation (11). The analysis of correlation matrix is shown in Table 7.
$M P I=\psi_{1} \times 0.695+\psi_{2} \times 0.251+\psi_{3} \times 0.054$
MPI has been treated as a single objective function and quality loss is calculated, which is to be minimized which is shown in Table 6.

Taguchi's Lowe the better (LB) criterion has been used to minimize the quality loss .Fig 2 shows $\mathrm{S} / \mathrm{N}$ ratio plot from with optimal factorial combination. The optimal setting is $\mathrm{I}_{4} \mathrm{~S}_{3} \mathrm{~V}_{1} \mathrm{~T}_{4} . \mathrm{S} / \mathrm{N}$ ratios are shown in Table 6.The result has been verified through confirmatory experiment, which showed satisfactory results. The maximum possible number of principal component to be computed is equal to the number of responses. In this study four responses selected.

Fig 2 Main plot for $\mathrm{S} / \mathrm{N}$ ratios.
Table 9. Response Table for Signal to Noise Ratios

| Level | I | S | V | T |
| :--- | :---: | :---: | :---: | :---: |
| 1 | -10.558 | -13.892 | 8.207 | -12.126 |
| 2 | -8.409 | -13.151 | -12.395 | -7.311 |
| 3 | -9.264 | 11.939 | -13.119 | -10.502 |
| 4 | 5.262 | -8.424 | -9.913 | 5.839 |
| 5 | -11.277 | -10.718 | -7.027 | -10.147 |
| Delta | 16.539 | 25.832 | 21.326 | 17.966 |
| Rank | 4 | 1 | 2 | 3 |

## 8. Analysis of Variance (ANOVA)

Analysis of variance (ANOVA) technique was used to test the adequacy of the model. This method is very useful to reveal the level of significance of influence of factors or interaction factors on particular response. It separates the total variability of responses into contributions rendered by each of parameter and error.

$$
\begin{equation*}
S S_{T}=S S_{F}+S S_{e} \tag{12}
\end{equation*}
$$

Where
$S_{T}=\sum_{j=1}^{p}\left(\gamma_{j}-\gamma_{m}\right)^{2}$
$S S_{T}=$ Total sum of squared deviations about the mean
$S S_{F}=$ Sum of squared deviations due to each other
$S S_{e}=$ Sum of squared deviations due to error
$\gamma_{j}=$ Mean response for $j^{\text {th }}$ experiment
$\gamma_{m=\text { Grand mean of responses }}$
Depending on F -value, P - value (probability of significance is calculated If P value is $95 \%$ confidence level then factors are significant.

Table 10 Analysis of Variance

| Source | DF | Adj SS | Adj MS | F-Value | P -Value |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Regression | 4 | 13.315 | 3.329 | 1.10 | 0.384 |
| I | 1 | 0.857 | 0.857 | 0.28 | 0.601 |
| S | 1 | 12.068 | 12.068 | 3.98 | 0.060 |
| V | 1 | 0.003 | 0.003 | 0.00 | 0.972 |
| T | 1 | 0.386 | 0.386 | 0.13 | 0.725 |
| Error | 20 | 60.610 | 3.030 |  |  |
| Total | 24 | 73.926 |  |  |  |

## 9. Validation of Models

The predicted quality loss $\gamma$ using the optimal level of design parameters can be calculated as:

$$
\begin{equation*}
\bar{\gamma}=\gamma_{m}+\sum_{i=0}^{p} \bar{\gamma}_{j}-\gamma_{m} \tag{13}
\end{equation*}
$$

Where $\gamma_{m}$ is the total mean quality loss and $\gamma$ is the
mean quality loss at the optimal level and p is the number of the main design parameters that affect the quality characteristics. Table 10 represents the comparison of the predicted bead geometry parameters with that of actual by using optimal welding conditions; good agreement between the two has been observed and improvement of overall $\mathrm{S} / \mathrm{N}$ ratio is the result. This proves the utility of the proposed approach in relation to process optimization, where more than one objective has to be fulfilled simultaneously.

Table 11 Results of conformity experiment

| Parameters | Initial factor setting | Prediction | Experiment |
| :--- | :---: | :---: | :---: |
| Level of factors | $\mathrm{I}_{1} \mathrm{~S}_{1} \mathrm{~V}_{1} \mathrm{~T}_{1}$ | $\mathrm{I}_{4} \mathrm{~S}_{3} \mathrm{~V}_{1} \mathrm{~T}_{4}$ | $\mathrm{I}_{4} \mathrm{~S}_{3} \mathrm{~V}_{1} \mathrm{~T}_{4}$ |
| Bead width | 18.567 | 16.134 | 17.225 |
| Reinforcement | 4.817 | 3.982 | 3.347 |
| Penetration | 2.202 | 2.125 | 2.985 |
| $\mathrm{D}(\%)$ | 42.161 | 40.131 | 40.643 |
| Overall S/N ratio | -14.618 | -7.822 | -7.639 |
| Improvement in S/N ratio | 8.660 |  |  |

## 10. Results and Discussions

In this study Taguchi's Lower-the better criteria has been used to minimize the quality loss. Fig 2 shows $\mathrm{S} / \mathrm{N}$ ratio with optimal parameter combination as $\mathrm{I}_{4} \mathrm{~S}_{3} \mathrm{~V}_{1} \mathrm{~T}_{4}$. This has been verified through confirmatory tests conducted. The maximum possible number of principal components computed is equal to the number of responses however in this case the fourth components accountability is zero hence it is neglected. This study deals with three principal components composite element. Then quality loss is calculated. Results of ANOVA in Table 10 indicate that voltage with high p value of 0.972 is the most effective parameter in this multi criteria optimization. Table 9 shows response table for signal to noise ratios. Table 11 shows conformity tests conducted as per optimization results. According to Taguchi' prediction formula predicted value of $\mathrm{S} / \mathrm{N}$ ratio for MPI becomes -7.820
whereas in confirmatory experiment it is obtained a value of -7.632. So quality has improved using the optimal setting. We can see that there is improvement in overall S/N ratio

## 11. Conclusions

In this study, a detailed methodology of PCA based hybrid Taguchi optimization technique has been presented for evaluating the bead geometry and parametric combinations in submerged arc welding process. The study proposes an integrated optimization approach using Principal Component Analysis (PCA) in combination with Taguchi's robust design methodology. The following conclusions may be drawn from the results of the experiments and analysis of the experimental data in connection with correlated multi-response optimization in submerged arc welding.

1. Application of PCA has been recommended to eliminate response correlation by converting correlated responses into uncorrelated quality indices called principal components which have been as treated as response variables for optimization.
2. Based on accountability proportion (AP) and cumulative accountability proportion (CAP), PCA analysis can reduce the number of response variables to be taken under consideration for optimization.
3. Based on accountability proportion (AP); treated as individual response weights, this method can combine individual principal components into a single multi response performance index (MPI) to be taken under consideration for optimization. This is really helpful in situations where large number of responses has to be optimized simultaneously.
4. The said approach can be recommended for continuous quality improvement and off-line quality control of a process/product
